Install Docker and Docker Compose

To install Docker-CE (Community Edition) and Docker Compose, you can open the terminal, or SSH into your host system, then use the command

`curl https://get.docker.com | sh`

You'll be prompted to enter you super user password, then the install should commence.

> NOTE: If you are using a system without sudo installed, you should install it, as this command seems to require it, even if you're logged in as root, which you really shouldn't be.

> If you happen to be using a Linux version that isn't supported by this one-liner command, you can find instructions to install Docker-CE and Docker Compose for your distro with a quick web search.

Finally, let's add our user to the docker group. This will allow us to use the `docker` and `docker compose` commands without using `sudo` every time. Use the command:

`sudo usermod -aG docker <username>`

Where you'll replace `<username>` with your actual name / username. In my case I would use

`sudo usermod -aG docker brian`

Now, you can either log out and back in to get the new group to take effect, or you can use the command:

`newgrp && newgrp docker`

which will allow you to act as part of the `docker` group temporarily until you can log out and back in later.
